

# 1 K-means clustering

Given  $N$  data points  $\{x_n\}_{n=1}^N \subset \mathbb{R}^D$ . Initialize  $K$  prototype vectors  $\{\mu_k\}_{k=1}^K$ . Each  $\mu_k$  corresponds to the mean of the  $k^{\text{th}}$  cluster. Let  $r_{nk}$  be indicator variable with respect to  $x_n$  and  $\mu_k$ .

$$r_{nk} = \begin{cases} 1 & \text{if } k = \arg \min \|x_n - \mu_k\|^2 \\ 0 & \text{otherwise} \end{cases}$$

Then update  $\mu_k$ ,

$$\mu_k = \frac{\sum_n r_{nk} x_n}{\sum_n r_{nk}}$$

Keep this procedure until

$$J = \sum_{n=1}^N \sum_{k=1}^K r_{nk} \|x_n - \mu_k\|^2$$

converge.
